## Namespace Documentation

### 1.1 drjanv Namespace Reference

#### Functions

- double [Legendre](#) (int N, double x)
- double [dLegendredx](#) (int N, double x)
- double [d2Legendredx2](#) (int N, double x)
- std::vector< double > [LegendreRoots](#) (unsigned int N, unsigned int max\_iters=1000, double tol=1.0e-12)
- std::pair< std::vector< double >, std::vector< double > > [GaussLegendreQuadrature](#) (unsigned int N, bool verbose=false, unsigned int max\_iters=1000, double tol=1.0e-12)
- template<typename T , typename D = int>  
std::vector< T > [Range](#) (T start, T end, D delta=1)

#### 1.1.1 Function Documentation

##### 1.1.1.1 Legendre()

```
double drjanv::Legendre (  
    int N,  
    double x )
```

Provides the function evaluation of the Legendre polynomial  $P_N$  at value x.

#### Parameters

$N$	int Order of the Legendre polynomial.
$x$	double The evaluation point.

### 1.1.1.2 dLegendredx()

```
double drjanv::dLegendredx (
    int N,
    double x )
```

Provides the function evaluation of the derivative of the Legendre polynomial  $\frac{dP_N}{dx}$  at value x.

#### Parameters

<i>N</i>	int Order of the Legendre polynomial.
<i>x</i>	double The evaluation point.

### 1.1.1.3 d2Legendredx2()

```
double drjanv::d2Legendredx2 (
    int N,
    double x )
```

Provides the function evaluation of the second derivative of the Legendre polynomial  $\frac{d^2P_N}{dx^2}$  at value x.

#### Parameters

<i>N</i>	int Order of the Legendre polynomial.
<i>x</i>	double The evaluation point.

### 1.1.1.4 LegendreRoots()

```
std::vector< double > drjanv::LegendreRoots (
    unsigned int N,
    unsigned int max_iters = 1000,
    double tol = 1.0e-12 )
```

Finds the roots of the Legendre polynomial.

The algorithm is that depicted in:

[1] Barrera-Figueroa, et al., "Multiple root finder algorithm for Legendre and Chebyshev polynomials via Newton's method", *Annales Mathematicae et Informaticae*, 33 (2006) pp. 3-13.

#### Parameters

<i>N</i>	Is the order of the polynomial.
<i>roots</i>	Is a reference to the roots.
<i>max_iters</i>	Maximum newton iterations to perform for each root. Default: 1000.
<i>tol</i>	Tolerance at which the newton iteration will be terminated. Default: 1.0e-12.

**Returns**

A `std::vector<double>` containing a sorted list of roots in the interval  $[-1,1]$ .

**Author**

Jan

**1.1.1.5 GaussLegendreQuadrature()**

```
std::pair< std::vector< double >, std::vector< double > > drjanv::GaussLegendreQuadrature (
    unsigned int N,
    bool verbose = false,
    unsigned int max_iters = 1000,
    double tol = 1.0e-12 )
```

Populates the abscissae and weights for a Gauss-Legendre quadrature given the number of desired quadrature points.

**Parameters**

<i>N</i>	Is the number of quadrature points.
<i>roots</i>	Is a reference to the roots.
<i>max_iters</i>	Maximum newton iterations to perform for each root. Default: 1000.
<i>tol</i>	Tolerance at which the newton iteration will be terminated. Default: 1.0e-12.

**Returns**

A pair with each part of type `std::vector<double>` and equal in size. The first part is a vector of quadrature points and the second part is a vector of weights.

**Author**

Jan

**1.1.1.6 Range()**

```
template<typename T , typename D = int>
std::vector< T > drjanv::Range (
    T start,
    T end,
    D delta = 1 )
```

Returns a range of number according to the logic of the parameters.

**Parameters**

<i>start</i>	First number in the sequence.
<i>end</i>	Termination criteria. If the delta is positive then the sequence will terminate if $i \geq \text{end}$ , otherwise if the delta is negative the sequence will terminate if $i \leq \text{end}$
<i>delta</i>	Cannot be 0. Default 1. Can be negative.

**Returns**

A `std::vector` of template type `T` containing the range according to the logic.

**Example:**

```
auto iorder = drjanv::Range<int>(0, 10); // 0,1,...,9
auto iorder = drjanv::Range<int>(9,-1,-1); //9,8,...,0
```
